#### **Abstract**

Market prices, roundwood costs, and other operating factors are used to formulate algorithms that may be used for estimating investment limits for small-scale SDR (Saw-Dry-Rip) and EGAR (Edge-Glue-and-Rip) sawmills. Algorithms are derived from results of discounted cash flow analyses approximating mills producing between 6 million and 12 million board feet per year (two-shift basis). The equations presented provide an approximating method which can be useful for assessing economic potentials for totally new mills, or modification of existing mills for production of SDR or EGAR lumber, and can be expected to be useful for structuring more detailed analyses for final assessments.

Keywords: SDR sawmills, EGAR sawmills, utilization economics, financial analysis.

## Investment Limits for Small-Scale SDR and EGAR Sawmills

George B. Harpole, Research Forester Forest Products Laboratory, Madison, WI

#### Introduction

A viable investment must produce an output that can be sold to generate enough revenue to cover operating costs, return capital investment, and produce sufficient profit to attract investment monies. Market prices, roundwood costs, and other operating costs essentially establish investment limits for new sawmills or converting old sawmills to new products. Using such operating factors, this paper provides equations for estimating maximum investments for building or converting a sawmill to use the SDR (Saw-Dry-Rip) and EGAR (Edge-Glue-and-Rip) processes to manufacture between 6 million and 12 million board feet (two-shift basis) of random length structural lumber per year from low- to medium-density hardwoods. This paper also includes examples for both new and converted mills, based on typical economic assumptions.

The equations are derived from discounted cash flow analyses and are linear, even though discounted cash flow analyses do not yield linear results when using different estimates for input. However, results are close enough to being linear to expect estimating errors to be approximately  $\pm 5$  percent of discounted cash flow results when estimates of change are within  $\pm 30$  percent of those used for deriving equations, as displayed in the appendix.

This procedure should only be used as a preliminary step to assess potential investment viability. All site-specific costs and related investment factors should be identified and used for more careful analysis to provide a basis for final assessment.

#### SDR and EGAR

The SDR process is innovative, enabling manufacture of quality structural lumber from low- to medium-density hardwoods by eliminating the traditional problem of warp. Logs are live sawn on the same plane into 7/4 (1-3/4-in.-thick) flitches (Boone and Maeglin 1980, Gerhards 1983, Maeglin 1978, Maeglin and Boone 1983). The flitches are rough edged to make compact kiln loads, dried to an average moisture content of  $\pm$  12 percent (dry basis), and then ripped to width and dressed for use.

EGAR mills are compatible with SDR mills and can utilize even small logs to produce lumber of any width from live-sawn flitches edge-glued together and ripped to the desired width (Bulgrin and others 1978, Kling 1979). SDR or EGAR are significant because they offer the opportunity to better utilize the 68 billion cubic feet of hardwoods now growing on U.S. commercial forest lands east of the Rocky Mountains (U.S. Department of Agriculture 1980).

## Size Limits for SDR and EGAR Mills

Economic efficiency of lumber manufacture is largely associated with a balance of equipment, labor, and management that maximizes productivity with respect to the fixed costs of facilities and management. For sawmills, the most economical size seems to be between 45 million and 60 million board feet per year (Harpole 1983, Harpole and others 1981). Less economic, but more realistic, mill sizes for many circumstances in the hardwood regions, however, suggest smaller mills designed to produce between 6 million and 12 million board feet per year. Smaller concentrations of timber and geographic barriers often limit mill size.

## Equations for New SDR and EGAR Mills

Investment limits for the SDR and EGAR mills were estimated using discounted cash flow techniques and previous economic evaluations of SDR and EGAR (Harpole 1983, Harpole and others 1981, Harpole and others 1979, Stumbo 1981).

The following equation may be used to estimate investment limits for SDR and EGAR sawmills and working capital requirements on the basis of other revenue, wood costs, and IRR assumptions.

$$SDR$L = (2.08 - (IRR*0.054))*((Q((2.15*AR) - (4.729*WC))) - 1,027,749)$$
(1) 
$$EGAR$L = (2.075 - (IRR*0.043))*((Q((1.9003*AR) - (4.3476*WC))) - 1,018,700$$
(2)

#### where

SDR\$L = investment limit for cost of SDR facility in dollars

EGAR\$L = investment limit for cost of EGAR facility in dollars

IRR = desired after-tax internal rate of return expressed as a percent

Q = output of lumber per year in thousands of board feet

AR = average realization for lumber in dollars per thousand board feet

WC = average cost for roundwood in dollars per cord (assumes 78 ft³ of solid wood per cord).

Working capital requirements must be estimated and added to the investment limit for facilities to estimate total investment limit. Working capital requirements may be estimated using the following equation:

$$SWK = 35,838 + (14.29 ^ Q)$$
 (3)  
 $EWK = 41,675 + (14.87 ^ Q)$  (4)

#### where

SWK = estimated working capital requirement for SDR mill in dollars

EWK = estimated working capital requirement for EGAR mill in dollars

Q = annual output of lumber in thousands of board feet. For a new EGAR mill, the following equations can be used to calculate investment limits.

Once an investment limit has been calculated, an approximate budget for various cost components for facilities construction can be calculated on the basis of assignments to known construction costs and distributions of any balance on the basis of estimated costs.

Table 1 presents the author's best estimate of likely distributions of costs to various construction categories, allowing 10 percent of the total investment limit to cover some disparities. If a sawmill cannot be constructed within given investment limits, then there should be serious concern to whether the project can be made economically viable.

Table 1.—Estimates of investment limits for SDR and EGAR sawmills producing 12 million board feet of lumber per year (1984 basis)

item	SDR r	nill²	EGAR	mill³
		Dol	(pct)	
Facilities investment limits Land and site preparation	\$ 122,500	(4.90)	\$ 122,500	(4.08)
Buildings	150,000	(6.00)	200,000	(6.67)
Processing equipment Dry kilns	1,427,500	, ,	1,777,500 300,000	
Mobile equipment*	250,000		300,000	, ,
Contingencies	250,000	(10.00)	300,000	(10.00)
Facilities total Working capitals	\$2,500,000 207,344	(100.00)	\$3,000,000 220,115	(100.00)
Investment limits, total	\$2,707,344		\$3,220,115	

<sup>&#</sup>x27;Components and relationship of costs largely derived from previous work by author (Harpole 1979 and 1983).

<sup>2</sup>Investment limits for SDR mill based on average realization of \$237/1,000 fbm and operating costs and tax allowances from tables A-1 and A-2.

Investment limits for EGAR mill based on average realization of \$280/1,000 fbm and operating costs and tax allowances from tables A-3 and A-4.

\*Assumes replacement of mobile equipment at end of fifth year of operating.

 $^{5}$ Working capital for SDR mill = \$35,838 + (\$14.29\*1,000 fbm output). Working capital for EGAR mill = \$41,675 + (\$14.87\*1,000 fbm output).

## **Equations for Modifying Mills** to Use SDR or EGAR

Because there are many situations where existing sawmills may be modified to allow production of SDR and EGAR lumber, estimating investment limits for such modifications can be useful. Equations (5) through (8) are based on the same assumptions and discounted cash flow analyses as equations (1) through (4) and may be used for estimating investment limits for mill modifications. The fundamental requirement for application of the following equations is that the candidate sawmill is similar to the described SDR or EGAR sawmill, except for facility components and their related operating costs that might be introduced to accomplish an SDR- or EGAR-operating standard. Estimated investment limits from equations (5) through (8) should be fairly accurate (±5 pct) for mills already producing from 6 million to 12 million board feet of lumber per year on a two-shift basis. For modifying sawmills with intentions to expand operations to a second-shift for producing SDR lumber, conventional engineering economy methods should be used for evaluation because of the effects of full-second shift labor, power, maintenance and other operating costs. Justification for using the following procedures for estimating investment limits is where SDR or EGAR lumber production only replace existing production of other types of wood products.

Equation (5) may be used to estimate investment limits associated with an increase in average lumber realization and/or reduction in wood costs. (That is, if some portion of ongoing production time is given to production of SDR lumber under conditions where the difference between revenues from lumber and associated wood costs is increased, the increase in profit contribution can be expected to provide a basis for new investment):

SDR 
$$L/\Delta R \& \sigma \Delta C = Q[\Delta R(4.4720 - 0.1161 * IRR) - \Delta C(9.8363 - 0.2554 * IRR)]$$
 (5)

EGAR \$L/
$$\Delta$$
AR &/or $\Delta$ WC =  $Q[\Delta$ AR(3.9431 - 0.0814 \* IRR) -  $\Delta$ WC(9.0213 - 0.1869 \* IRR)] (6)

#### where

SDR \$L = change for SDR investment limit in dollars

EGAR \$L = change for EGAR investment limit in dollars

ΔAR = expected change in average realization expressed in dollars

ΔWC = expected change in average costs for roundwood expressed in dollars per cord (78 ft³ solid wood per cord)

Q = current annual volume of lumber output to be converted to SDR

production in thousands of board feet IRR = internal rate of return desired for investment monies, expressed as a percent (should be same as rate-ofreturn for current operations). Equations (7) and (8) may be used to estimate a change in investment limits associated with a change in production volume due to a shift to SDR or EGAR manufacture. Production could either be increased, or decreased. A decrease in production volume will cause a reduction in the investment limit that might be calculated on the basis of increased lumber realization and/or reduction in wood costs. For most hardwood mills, either the same production volume or an increase in production volume should be realized.

SDR 
$$L/\Delta Q = \Delta Q[AR(4.4720 - 0.1161 * IRR - WC(9.8363 - 0.2554 * IRR)]$$
 (7)

EGAR 
$$L/\Delta Q = \Delta Q[AR(3.9431 - 0.0814 * IRR) - WC(9.0213 - 0.1869 * IRR)]$$
 (8)

#### where

ΔQ = expected change in sawmill lumber output per year, expressed in thousands of board feet

AR = average realization for lumber output in dollars per thousand board feet

 WC – average cost for roundwood expressed as dollars per cord, assuming 78 ft³ of solid wood per cord.

## Sample Applications of the Equations

The equations presented in this paper were used to calculate the investment limits for new SDR and EGAR mills and for converting existing mills to the SDR and EGAR processes.

#### **Assumptions**

Calculations of the investment limits for the SDR and EGAR processes were based on the following assumptions:

Revenues.—The estimates of revenues which would be produced by the type of mills included in this study were based on the free on board (f.o.b.) mill prices for southern pine framing lumber, produced in sawmills in the southeastern United States, during a recent 5-year period (Random Lengths 1979 through 1983). The high prices used in this study were from the October 5, 1979, price report; low prices were from the April 25, 1980, price report; and average prices are the average of these high and low prices (table 1). The average model prices used for analysis was \$237 per thousand board feet for SDR random length, random width lumber, and \$280 per thousand board feet for EGAR random length, 10- and 12-inch-wide lumber.

Prices.—Southern pine framing lumber prices were used because this product would be competitive with low- to medium-density hardwood lumber. The shipping distances from primary market centers are also comparable and shipping weights about equal. Low- to medium-density hardwoods (specific gravity of 0.45 or less) cannot be expected to compete with southern pine for engineered uses on a one-to-one basis because of lower strength properties. Such species as yellow-poplar and sweetgum, however, can be used in truss fabrication and wall framing where their strength properties will satisfy design specifications. Price differentials that may result from use limitations are not speculated upon here.

**Vield.**—Using lumber recovery predicted by the Best Opening Face (BOF) program (Lewis and Hallock 1973) and a sample of log sizes ranging in diameter from 5 to 12 inches, we computed f.o.b. mill value of the SDR product mix to be about \$237 per thousand board feet—based on average prices (tables 2 and 3). This figure is based on the following recovery estimates:

Dimensions (85 pct, 10 ft and longer)

2 by 4, 25 pct 2 by 6, 19 pct 2 by 9, 40 pct 2 by 10, 13 pct 2 by 12, 3 pct

2 by 6 No. 2 and Better, 90 pct

No. 2, 10 pct

On the same basis, an EGAR mill would average from \$270 to \$340 per thousand board feet, depending on whether 2 by 10's or 2 by 12's are produced. On this basis, an EGAR mill might average from \$33 to \$103 per thousand board feet more than an SDR mill. This assumes that about the same demand and scarcity of supply will continue for wide-dimension lumber (2 by 10's and 2 by 12's). Floor trusses manufactured from 2 by 3's and 2 by 4's have been replacing wide lumber in many applications. This replacement will continue, of course, only as long as inplace costs for fabricated trusses remain competitive with those of wide-width lumber. Potential investors in new sawmills should consider this factor.

**Wood Costs.**—Wood costs were assumed to be \$45/cord (78-ft³ solid wood/cord). Low wood cost is an important factor to economic attractiveness of SDR and EGAR lumber manufacture. Because approximately one-half of all log volumes are transformed into residues, even with high levels of sawmilling efficiency, a dollar change in wood costs has approximately twice the effect of a dollar change in lumber realization. A reduction in wood costs and/or increase in lumber realization will often provide a substantial basis for new investment.

Other Assumptions.—A productive life of 10 years was assumed for mills using both systems. Other assumptions related to analysis are reflected from the discounted cash flow analyses displayed in the appendix and estimates presented in tables 1 through 5.

The results for SDR are based on assumptions of an after-tax IRR' of 20 percent, an average price of \$237 per thousand board feet for lumber, and an average wood cost of \$45 per cord (1984 basis). Working capital requirements are based on operating costs indicated in tables 2 through 5. The results for EGAR are based on assumption of an after-tax IRR of 25 percent, an average price of \$280 per thousand board feet for lumber, and an average wood cost of \$45 per cord.

<sup>&#</sup>x27;IRR is rate of return on all monies required to finance a project.

### Investment Limits for a New SDR Mill

Based on the best estimates available and given assumptions, up to \$2,500,000 could be viably spent for construction of an SDR sawmill rated for 12 million board feet of output per year but only \$753,000 for an SDR sawmill rated for 6 million board feet per year, using equation (1). Also, see tables A1 and A2.

### Investment Limits for a New EGAR Mill

Based on the best estimates available and given assumptions, up to \$3 million could be viably spent for construction of an EGAR sawmill rated for 12 million board feet of output per year, but only \$1 million for an EGAR sawmill rated for 6 million board feet per year, using equation (2). Also, see tables A3 and A4.

## Investment Limits for Modifying a Mill for SDR

In a mill modified for the SDR process, a \$10 per cord reduction in wood costs and \$10 per thousand board foot increase in lumber realization will provide a basis for an investment limit of \$206,349—assuming a 20 percent after tax return on investment for 3 million board feet of SDR lumber manufacture per year. This estimate is calculated using equation (5). This calculation assumes there will be no change in the annual average volume of lumber ouput.

Assuming mill modification will effect an increase of 200 thousand board feet of lumber production per year, via SDR lumber manufacture, such an increase would provide basis for an investment limit of \$59,355—assuming a 20 percent return on investment, an average realization for lumber of \$237 per thousand board feet, and wood costs of \$45 per cord. This is an additional investment limit that may be added to the previous calculation, which would provide a total investment limit of \$265,704. This estimate is calculated using equation (7).

Table 2.—Estimates of roundwood input and product outputs per thousand board feet of lumber output for SDR and EGAR sawmills

Item	Type of sa	wmill
item	SDR	EGAR
	Ovendry	on ——

The Forest Products
Laboratory (USDA Forest
Service) has served as the
national center for wood
utilization research si. 39
1910. The Laboratory, on the
University of WisconsinMadison campus, has
achieved worldwide
recognition for its
contribution to the knowledge
and better use of wood.

Early research at the Laboratory helped establish U.S. industries that produce pulp and paper, lumber, structural beams, plywood. particleboard and wood furniture, and other wood products. Studies now in progress provide a basis for more effective management and use of our timber resource by answering critical questions on its basic characteristics and on its conversion for use in a variety of consumer applications.

Unanswered questions remain and new ones will arise because of changes in the timber resource and increased use of wood products. As we approach the 21st Century, scientists at the Forest Products Laboratory will continue to meet the challenge posed by these questions.
